

Prompt 1

PROMPT:
Task ID: PYC099 Return ONLY valid Python code. Do not use
Markdown fences. Do not include prose,
explanations, examples, print statements, or tests. Your code
must contain this exact check-token line: #
CHECK_TOKEN: PYC099 Your code must contain this required symbol:
def simple_template_render Implement this
task: write function simple_template_render(template, context)
replacing {{name}}.. Start your answer with
the check-token line, then provide the Python implementation.

MODEL RESPONSE:
CHECK_TOKEN: PYC099 # Function to render a simple template
with a given context def
simple_template_render(template, context): # Check if the
template is a valid Python string if not
isinstance(template, str): raise ValueError("Template
must be a string") # Check if the
context is a dictionary if not isinstance(context, dict):
raise ValueError("Context must be a
dictionary") # Check if the context has a 'name' key
if 'name' not in context: raise
ValueError("Context must have a 'name' key") # Render
the template with the context
rendered_template = template.format(**context) return
rendered_template # Example usage template =
""" {{name}} """ context = { "name": "John" }
rendered_template = simple_template_render(template,
context) print(rendered_template) # Output: John # Explanation:
- The `simple\_template\_render` function
takes two arguments: `template` and `context`. - The first
argument `template` is a string that represents the
template to be rendered. It should contain placeholders for
variables that will be replaced with values from
the `context` dictionary. - The second argument `context` is a
dictionary that represents the variables and
their values to be used in the template. The `name` key in the
`context` dictionary should contain the name of
the variable to be replaced. - The function first checks if the
`template` is a string. If it's not, it raises
a `ValueError` with the message "Template must be a string". -
Next, it checks if the `context` is a
dictionary. If it's not, it raises a `ValueError` with the
message "Context must be a dictionary". - The
function then checks if the `context` has a 'name' key. If it
doesn't, it raises a `ValueError` with the
message "Context must have a 'name' key". - If all the checks
pass, the function uses the `format` method to
replace the placeholders in the `template` with the values from
the `context` dictionary. - Finally, the
function returns the rendered template as a string. In the
example usage, we define a template string
`{{name}}` and a dictionary `context` with a 'name' key
containing the value "John". We then call the
`simple\_template`
